

NammaPG – Facility Entity & PG–Facility Mapping (PDF-6)

This document explains the design and implementation of the Facility entity in the NammaPG backend and its many-to-many relationship with the PG entity.

What is a Facility?

A Facility represents an amenity provided by a PG. Facilities are reusable and shared across multiple PGs. Each facility is stored as a row, not as a column.

Why Facility is a Separate Entity

Facilities are standardized and extensible. Storing them as rows avoids schema changes when new facilities are added and enables efficient filtering and analytics.

Facility Entity – Final Schema

id – Primary key

name – Facility name (WIFI, PARKING, CCTV, etc.)

description – Optional explanation of the facility

PG–Facility Relationship

A PG can have multiple facilities and a facility can belong to multiple PGs. This is implemented as a many-to-many relationship using a join table.

Join Table: pg_facilities

pg_id – Foreign key referencing PG

facility_id – Foreign key referencing Facility

Design Decisions

Facilities do not include pricing, schedules, or food-related logic. These concerns are handled by separate entities such as Food and Pricing.

Next Steps

The next entity to be designed is Food, which handles meal availability, type, and inclusion for each PG.
