

NammaPG – PG Entity & Schema Design (PDF-4)

This document explains the design of the PG (Paying Guest) entity in the NammaPG backend system. The PG entity represents a physical property and is kept independent of users, rooms, facilities, and bookings.

Why PG is a Separate Entity

A PG is a property, not a person. Even though a PG has an owner, the owner is represented by the User entity. To avoid duplication and ensure scalability, PG information is stored in its own table.

Final PG Schema Fields

id – Primary key
name – Name of the PG
description – Details about the PG
gender – BOYS / GIRLS / COLIVING
totalFloors – Number of floors in the building
totalRooms – Total rooms in the PG
rating – Average rating of the PG
area – Area or locality
city – City name
active – Soft enable/disable flag
owner_id – Foreign key reference to User
createdAt – Creation timestamp
updatedAt – Last update timestamp

Relationships

One User (Owner) can manage multiple PGs, and each PG has exactly one owner. This relationship is implemented using @ManyToOne.

Design Decisions

Rooms, facilities, and bookings are intentionally kept separate. Owner details are not duplicated. Gender is stored as String for Phase-1 simplicity.

Next Steps

The next entity to be designed is Room, where room types, sharing, and capacity will be handled.
